Bone-Targeted Antigen to the Joints. Although there is evidence for a Th1 immune response during leishmaniasis, there is also evidence for a Th2-like response associated with lupus erythematosus (LE) pathogenesis. There is evidence that the host response to infection can trigger the onset of autoimmunity. In this regard, we previously demonstrated the presence of antinuclear antibodies (ANAs) in dogs with visceral leishmaniasis (VL). Therefore, to further understand the relationship between systemic autoimmunity and VL disease, we investigated the presence and cellular phenotype of VL antigens within the joints of dogs with VL. If VL antigens are present in joints and if leukocytes/mast cells are a source of VL antigens, then we would predict that the presence of LE lesions in the mast cell/basophil-rich area of a joint would be associated with the presence of VL antigens within the joint. Therefore, to begin to understand the relationship between VL and LE, we evaluated the presence of VL antigens within the joints of dogs with VL. In this case-control study, we enrolled 50 dogs: 20 dogs with VL caused by

Leishmania infantum and 30 dogs with no evidence of clinical or clinicopathologic signs of VL. We evaluated the prevalence of antileishmanial antibodies (ELISA and immunofluorescence assay) and the presence of antileishmanial antibodies (ELISA and immunofluorescence assay) and the presence of antileishmanial antibodies (TSA®) within the joint fluid of these dogs. We found a higher percentage of mast cells within the joint fluid of dogs with VL in comparison to
